S5_Adv_WeB_Projet

Matking Restaurant Web Application

Objective

Create a complete web application including:

- A Frontend using HTML, CSS and JavaScript
- A Backend to handle the application's logic
- An SQL database
- Communication between the Frontend, Backend and database

Team Members

- Mathis Poisson
- Julie Sieux

Technologies

- HTML / CSS / JavaScript
- SQL
- Git / GitHub

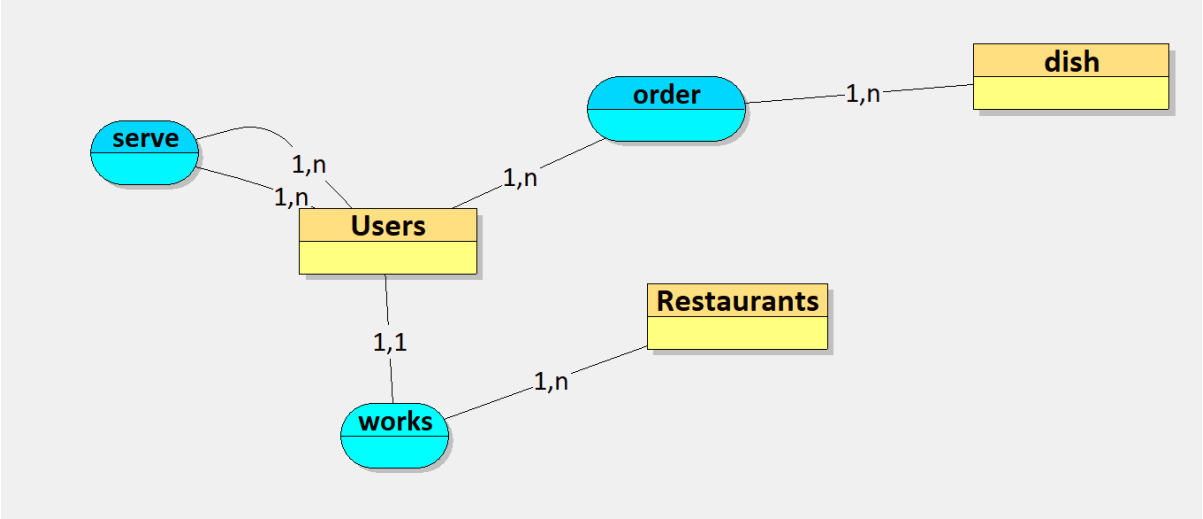

Contents

- ER diagram
- MDL (logical data model)
- Detailed use case diagram
- Project-level use case diagram
- Planned Gantt chart (weeks)

Diagrams

1. ER diagram

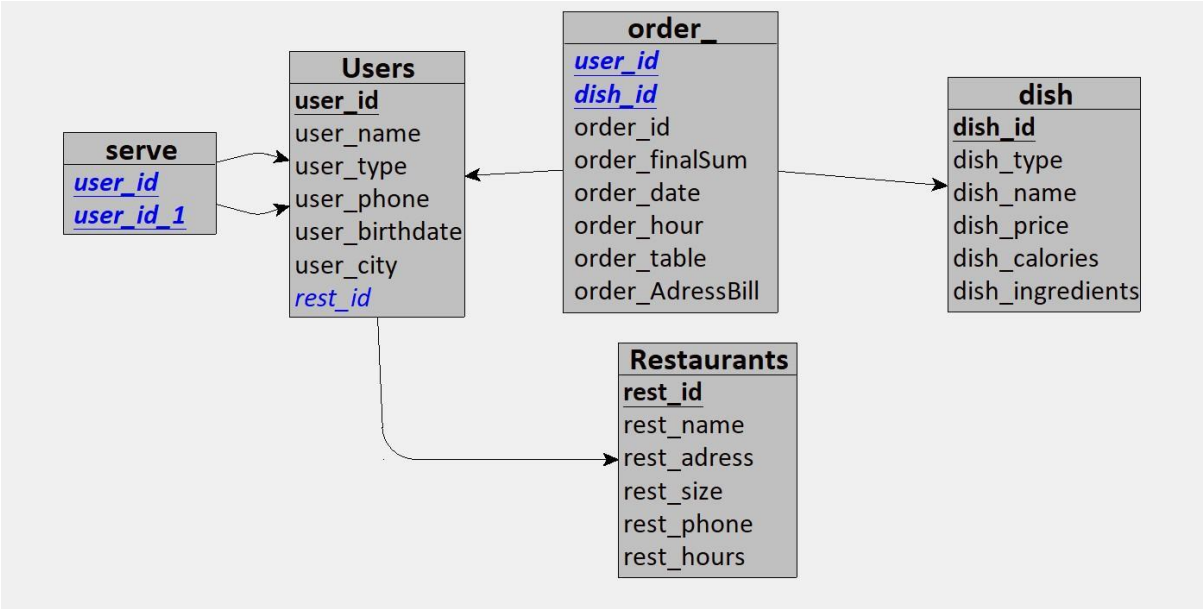

This diagram shows what information the application keeps track of and how the pieces relate to each other. For example, it shows that users can place orders, that orders contain dishes, and that employees work in a restaurant.

ER diagram

2. MDL (logical data model)

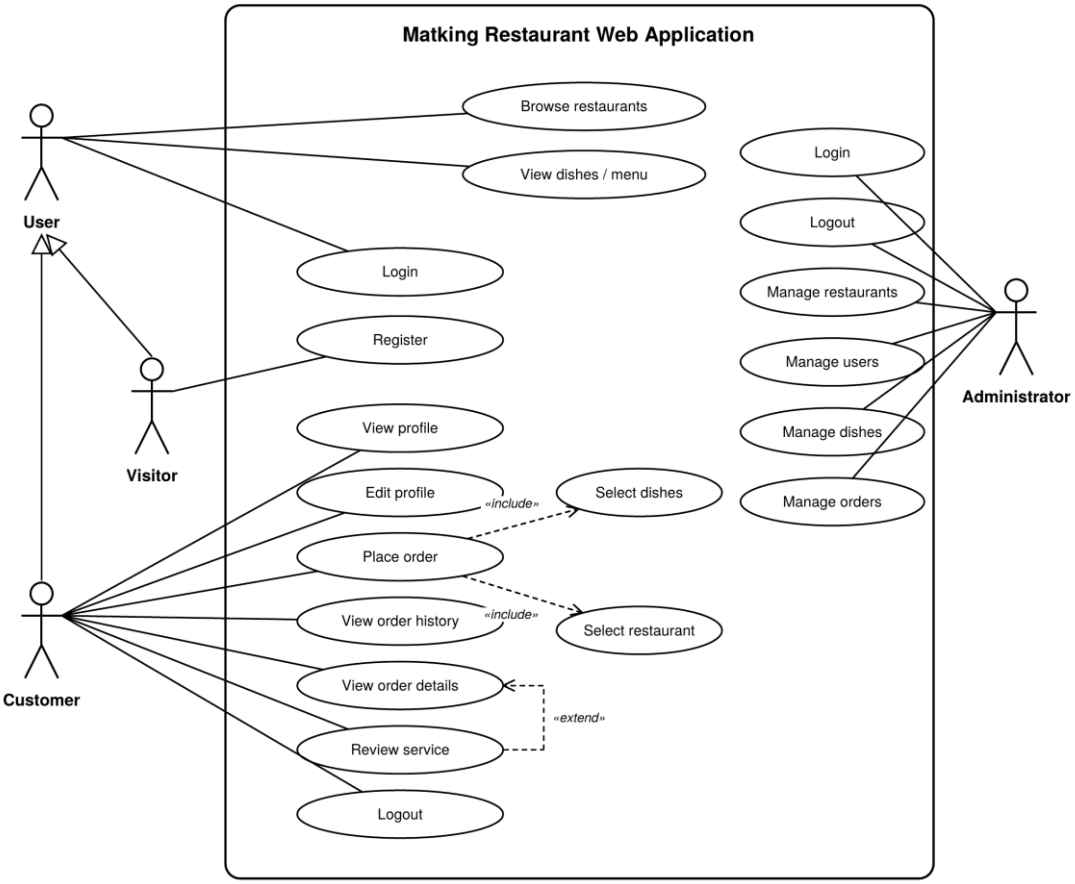

This is the technical version of the ER diagram, written as the tables of the database. It shows exactly how informations will be organized and linked behind the scenes, for example how an order is connected to the customer who placed it and the dishes they chose.

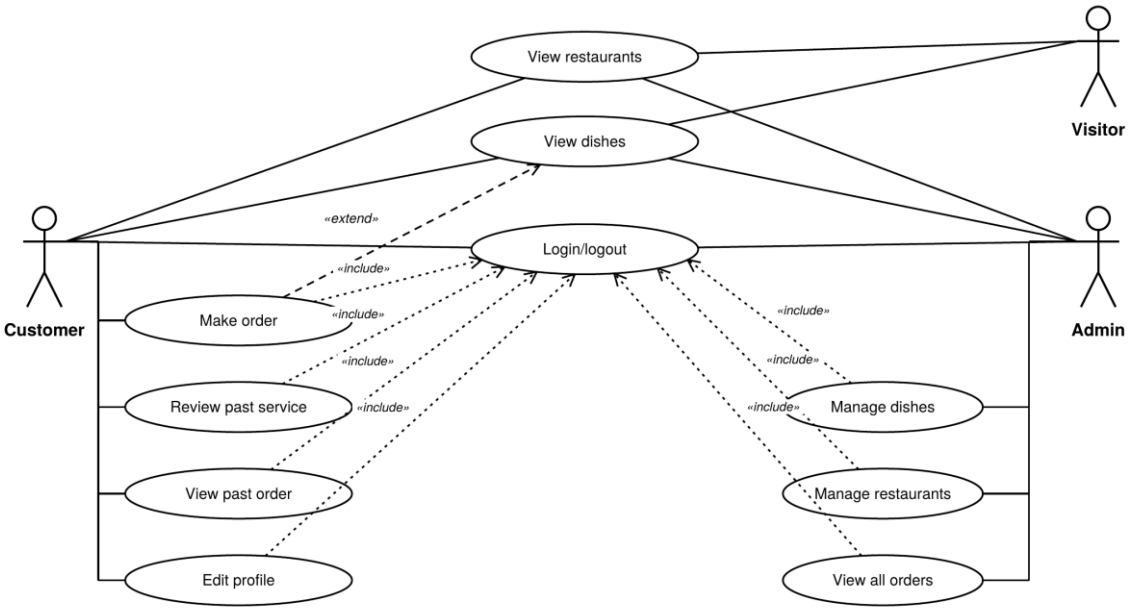

MDL, show FK keys

3. Detailed use case diagram

Those diagram shows what each type of person can do on the website. A visitor can browse restaurants and dishes, a customer can also place orders and manage their profile, and an administrator can manage the content. It is like a list of features, and who is allowed to use each one.

4. Planned Gantt chart

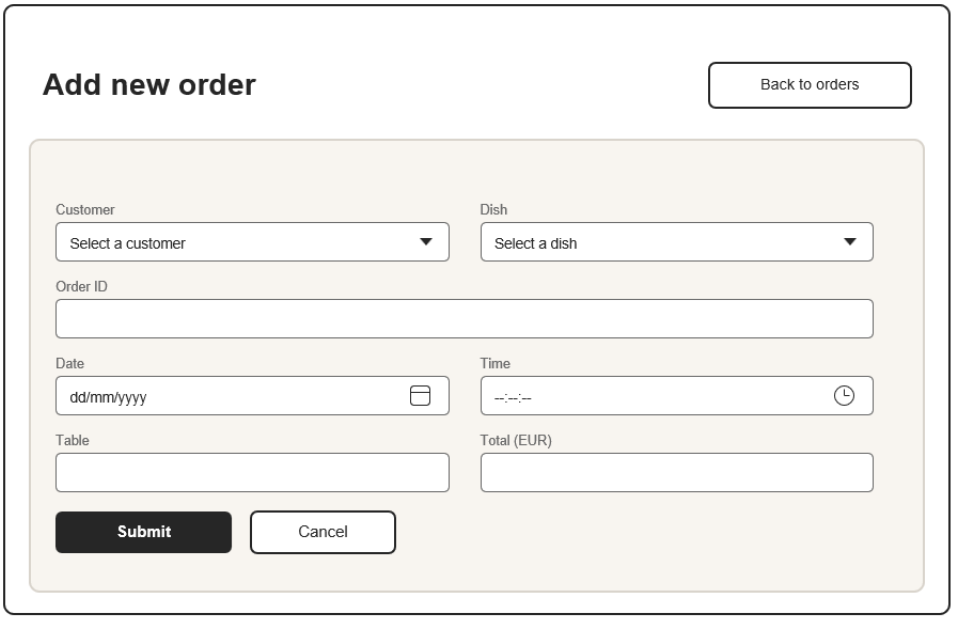

This is the project schedule. Each line is a task or a feature, and each bar shows during which weeks we work on it. It tells what will be ready and when, to follow our progress week by week and plan the tests and feedback.

Planned Gantt Chart. This planned Gantt chart presents the development schedule of the project over 16 weeks. It includes the main milestones for database design, frontend development, UML documentation, backend implementation, integration, authentication, testing and final delivery. Use case rows carry the same labels as the project-level use case diagram.

5. Wireframe

A wireframe is a simple, low-detail sketch of a screen. It shows the layout of a page and where each element goes (titles, buttons, input fields, menus), without final colors, images or styling. Its goal is to agree on the structure and the user experience before any code is written. It answers the question: *what will this functionality look like for the user?*

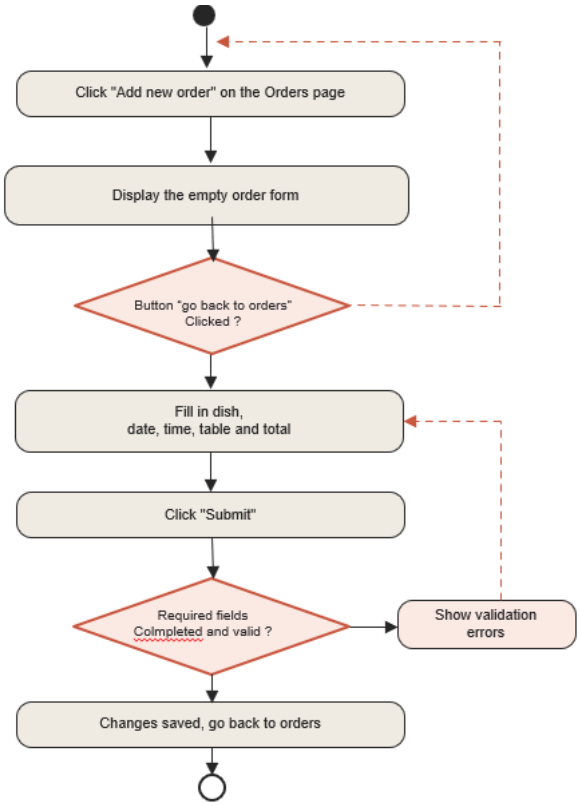

SIEUX Julie, Wireframe of the page Create orders

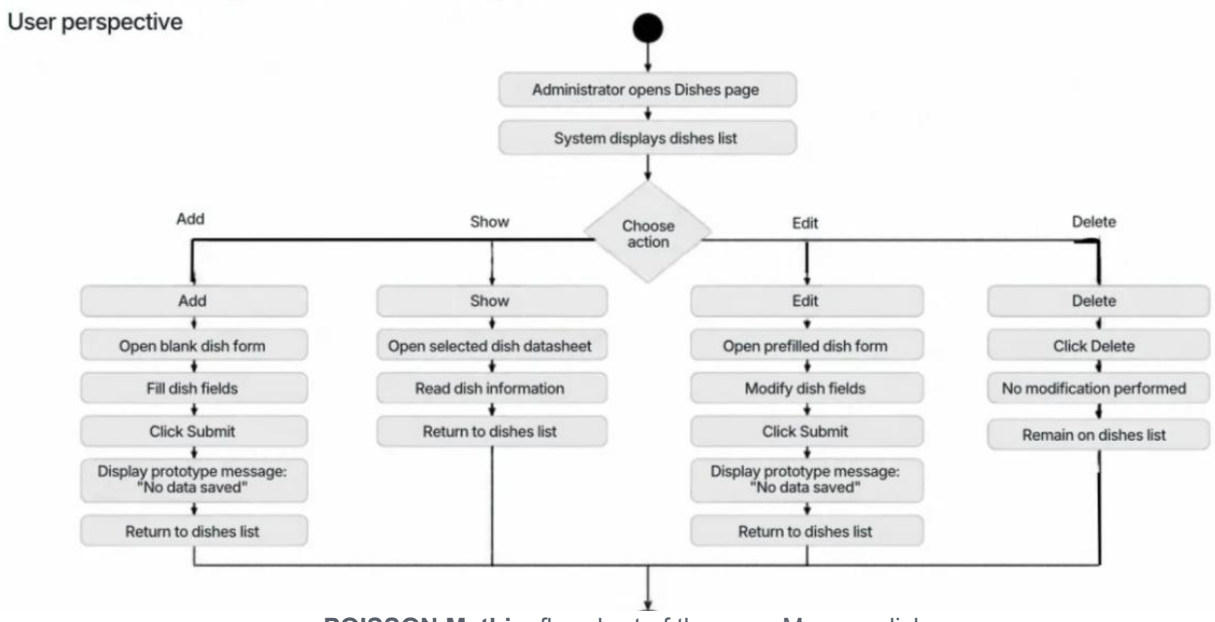

POISSON Mathis, Wireframe of the page Manage dishes

6. Flowchart

An activity diagram, also called a flowchart, represents the steps of a process from start to finish. It uses actions, decisions (for example “is the form valid?”) and arrows to show the possible paths, including errors and alternatives. In our case it follows the user’s actions and the system’s responses. It answers the question: *how does this functionality work from the user’s perspective?*

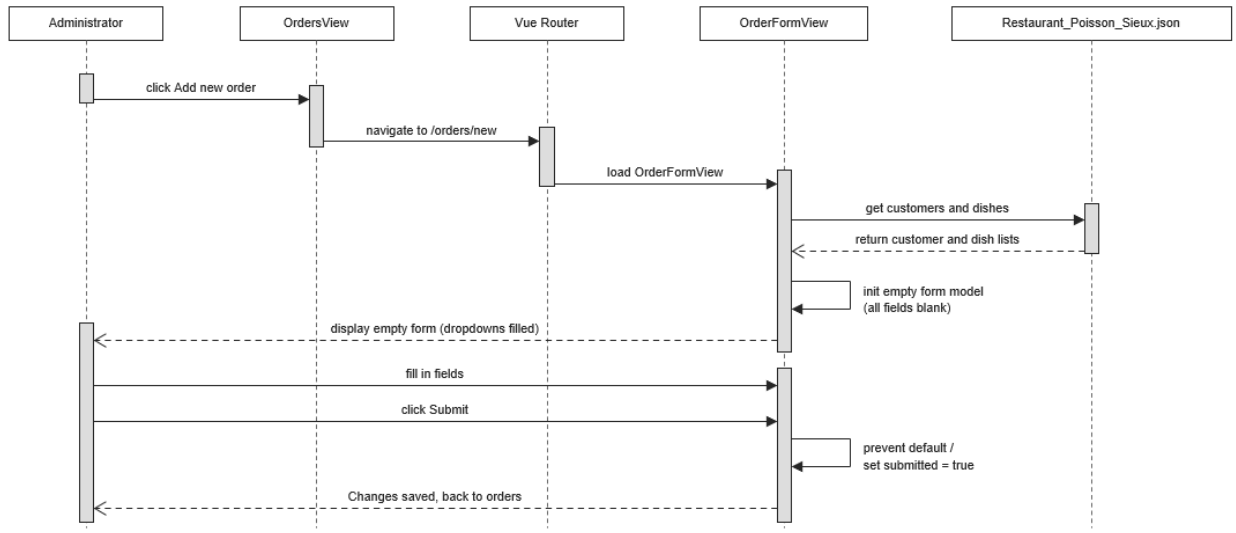

SIEUX Julie, flowchart of the page Create orders

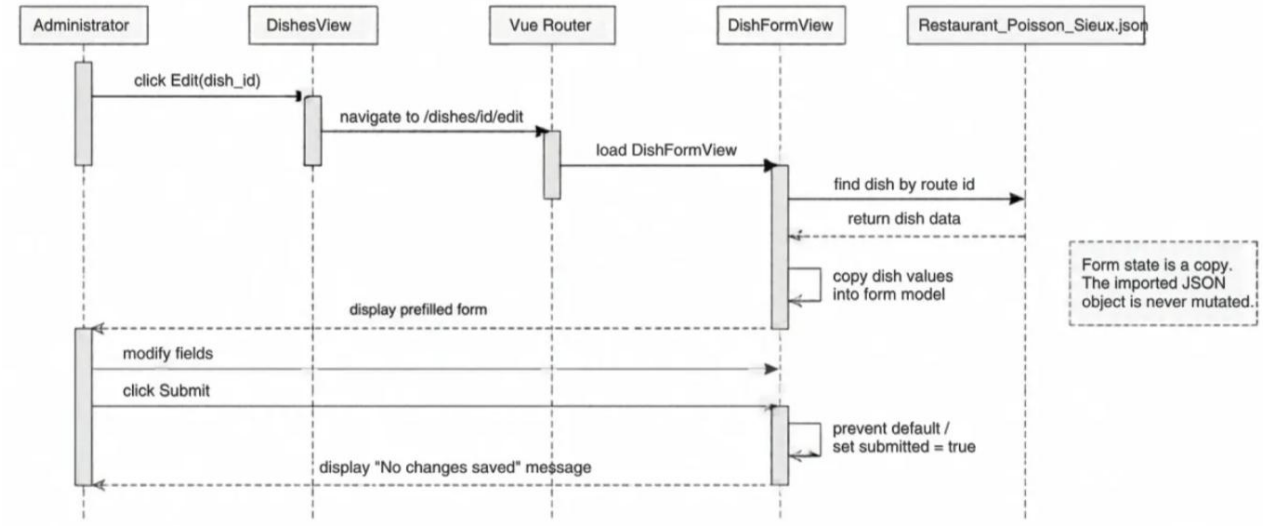

POISSON Mathis, flowchart of the page Manage dishes

7. Sequence diagram

A sequence diagram shows how the different parts of the code communicate over time. Each component (views, router, data source) has a vertical lifeline, and horizontal arrows represent the messages exchanged between them, from top to bottom in chronological order. Solid arrows are requests and dashed arrows are responses. It answers the question: *how does this functionality work from the code's perspective?*
